

Week 2 - MPI

K200353

Mohsin Ali Mirza

## Cluster Diagram:

**Problem:** If we wish to sum a large array of integers, then this will require a lot of ~~time~~ execution time therefore we can make this process go faster by using Distributed Memory Machine.

## Workflow:

Assume that we have 100 computers & that the memory space is of 100K is divided into 10K segments.

For adding total sum / reading the arr.

We will be using SPMD approach rather than SMP, because a single program with multiple data will be divided into multiple computers.

## Pseudo Codes:

```
if (nodeId == 0) // Master
```

```
{  
  readFromFile(arr, "___");
```

```
  for (foreach (10k integer in arr)
```

```
{
```

```
    startRange = ( );
```

```
    EndRange = ( ); send node
```

```
    MPI_Send (... 0, ...)
```

↑  
Receive node

```
}
```

```
do_processing(arr);
```

```
foreach (10k integers in arr)
```

```
{ MPI_Recv( ); }
```

```
print( );
```

```
}
```

```
else // Slave
```

```
{ MPI_Recv( ... 0 );
```

```
  Do_processing( );
```

```
  MPI_send (result, 0);
```

```
}
```

## Notes

Master Node

Read the all numbers

Distribute the 10k  
segments of integers  
to each computer  
(Sender master,  
Receiver Slaves)

Sum individual batch  
because master will also  
sum its own 10k integers  
read each result & then  
sum to final result.  
Prints the final result

For slaves

- Wait after loop because  
individual computer.
- sum ~~each~~ 10k integers  
send the each result
